

Analysis of Dataset Obtained from the Harmonic Oscillator Simulation Lab

Paul Ndulue

1 Introduction

This report presents a detailed analysis of the data obtained from simulating the motion of a damped, driven simple pendulum. The kinematics (displacement, velocity, and acceleration), the energy flow (potential, kinetic, and total mechanical energy), the stability of the physical parameters (amplitude, period, frequency, and angular frequency) over time, and the phase-space trajectories of the system are investigated here.

2 Theory

The motion of a simple pendulum is described by the second-order differential equation:

$$\ddot{\theta} + \frac{g}{l} \sin \theta = 0 \quad (1)$$

where the angular frequency is $\omega_0 = \sqrt{g/l}$ and period $T = 2\pi/\omega_0$.

Hence, eq. (1) can be rewritten as:

$$\ddot{\theta} + \omega_0^2 \sin \theta = 0 \quad (2)$$

This equation can be solved numerically using the Runge-Kutta (RK4) method to obtain the angular displacement as a function of time $\theta(t)$, angular velocity $\dot{\theta}(t)$, and angular acceleration $\ddot{\theta}(t)$.

The energy of the system can be calculated as:

$$E = \frac{1}{2}ml^2\dot{\theta}^2 + mgl(1 - \cos \theta) \quad (3)$$

Under linear damping and a time-varying driving force, $F_d \cos \omega_d t$ eq. (2) and eq. (3) become:

$$\ddot{\theta} + \gamma\dot{\theta} + \omega_0^2 \sin \theta = A_d \cos \omega_d t \quad (4)$$

where,

- $\gamma = \frac{b}{ml^2}$, is the damping factor,

- ω_d is the driving angular frequency, and
- $A_d = \frac{F}{ml}$, is the amplitude of the driving angular acceleration.

The period and frequency under these conditions become:

$$T = 2\pi\sqrt{\frac{l}{g}} \left(1 + \frac{1}{4} \sin^2 \frac{\Theta}{2} + \frac{9}{64} \sin^4 \frac{\Theta}{2} + \dots \right) \quad (5)$$

$$f = \frac{1}{2\pi} \sqrt{\frac{g}{l}} \left(1 - \frac{1}{4} \sin^2 \frac{\Theta}{2} - \frac{9}{64} \sin^4 \frac{\Theta}{2} + \dots \right) \quad (6)$$

3 Data and Analysis

For the simulation the following constant parameters were set:

1. Mass of the pendulum (m): 1 kg
2. Length of pendulum (l): 3 m
3. Damping coefficient (b): 0.05 kg s^{-1}
4. Driving torque amplitude (τ_d): 1 N m
5. Driving frequency (ω_d): 1.8 rad s^{-1}
6. Natural frequency (ω_0): 1.8 rad s^{-1}

The following initial conditions were also set:

1. Angular displacement(θ): 0.1 rad
2. Angular velocity ($\dot{\theta}$): 0.0 rad s^{-1}

The following observations were made from the data analysis of the simulation:

3.1 Kinematics

For each of the kinematic variables of displacement, velocity, acceleration and torque, the following trends were observed:

- The data set can be divided into regions at varying intervals called beats.
- The amplitude and width of these beats decrease over time.
- Fitting a trend line, we see that the crests and troughs of the beats approach a constant value and the beats fuse into one.
- steady-state value of the amplitude is approximately 0.7 rad , velocity 1.2 rad s^{-1} , and acceleration 2 rad s^{-2} .

3.2 Energy

Analysis of the energy data of the system shows that:

- the total mechanical energy of the system is not conserved.
- the potential and kinetic energies oscillate in a periodic manner, with the total energy decreasing over time due to damping.
- this decline of total energy caused by damping is counteracted by the driving torque, resulting in a constant energy value in the steady state.
- the steady-state value of the total energy is approximately 6 J.

System parameters

Analysis of the following system parameters: amplitude, period, frequency, and angular frequency shows that:

- Crests and troughs of the amplitude, period, frequency, and angular frequency graphs shrink to give steady-state values of approximately 0.7 rad, 3.555 s, 0.28 Hz, and 1.76 rad s⁻¹ respectively.
- The period is affected more by damping than by the driving force, evident by the greater decay of the upper envelope than the growth of the lower envelope.
- The amplitude, frequency, and angular frequency are affected more by the driving force than by damping, as evident in the boundary trends.

Figure 3: Amplitude, period, frequency, and angular frequency as functions of time.

3.3 Phase space

Plotting the phase space trajectory of the system the following observations were made:

- At the start of the motion (0 to 100s), the pendulum attains its absolute maximum velocity ($\approx 2 \text{ rad s}^{-1}$) and displacement ($\approx 1 \text{ rad}$).

- Over 0 to 600s, the graph begins to concentrate in the middle.
- From 1500 to 2000s, the loops settle into a single steady-state loop - evidence of the stabilization of energy.
- the velocity and displacement in steady-state correspond to those obtained from the kinematic analysis.

Figure 4: Phase space trajectory of the system.

4 Conclusion

This simulation shows that

- the motion of a simple pendulum under the influence of damping can be made to behave like one without damping if an appropriate driving force of specific magnitude and frequency is applied.
- the kinematic variables of the system (displacement, velocity, and acceleration) as well as the energy flow (potential, kinetic, and total mechanical energy) stabilize to a simple harmonic behaviour, without beats, in the steady state.

- the system parameters (amplitude, period, frequency, and angular frequency) also stabilize to constant values in the steady state.
- finally, the phase space trajectory of the system shows that the system settles into a single steady-state loop in the long term.
